Keywords: Dualized Logic Program, Supported Model, 3-valued, Vector Space.

#### Abstract

We propose a linear algebraic approach to computing 2 -valued and 3 -valued completion semantics of finite propositional normal logic programs in vector spaces. We first consider 3-valued completion semantics and construct the least 3 -valued model of comp(DB), i.e. the iff (if-and-only-if) completion of a propositional normal logic program DB in Kleene's 3-valued logic which has three truth values $\{\mathbf{t}$ (true), $\mathbf{f}$ (false), $\perp$ (undefined) $\}$. The construction is carried out in a vector space by matrix operations applied to the matricized version of a dualized logic program $\mathrm{DB}^{d}$ of DB . $\mathrm{DB}^{d}$ is a definite clause program compiled from DB and used to compute the success set $P_{\infty}$ as true atoms and finite failure set $N_{\infty}$ as false atoms that constitute the least 3 -valued model $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ of comp(DB). We then construct a supported model of DB, i.e. a 2 -valued model of comp(DB) by carefully assigning $\mathbf{t}$ or $\mathbf{f}$ to undefined atoms not in $P_{\infty}$ or $N_{\infty}$ so that the resulting model is 2-valued and supported. The assigning process is guided by an atom dependency relation on undefined atoms. We implemented our proposal by matrix operations and conducted an experiment with random normal logic programs which demonstrated the effectiveness of our linear algebraic approach to computing completion semantics.

## 1 INTRODUCTION

Performing logical inference in vector spaces has been studied as an attractive alternative to the traditional symbolic inference which opens a way to take advantage of flexible matrix operations in vector spaces and associated parallelism supported by recent computer technologies (Sato, 2017; Sakama et al., 2017; Sato et al., 2018). For example it was demonstrated Datalog programs can be computed orders of magnitude faster in vector spaces than by symbolic computation when relations are not too sparse (Sato, 2017). Also it is possible to invent new relations for more than $10^{4}$ entities from real knowledge graphs by reformulating abduction in vector spaces (Sato et al., 2018). In this paper, along the same line, we develop a linear algebraic approach to computing completion semantics of logic programs in vector spaces.

[^0]We first consider 3-valued completion semantics and construct the least 3 -valued model of comp(DB) where $\operatorname{comp}(\mathrm{DB})$ is the iff (if-and-only-if) completion of a finite propositional normal logic program DB as the 3-valued denotation of DB, in Kleene's 3-valued logic which is based on three truth values $\{\mathbf{t}($ true $)$, $\mathbf{f}$ (false), $\perp$ (undefined) (Fitting, 1985; Kunen, 1987). We prove that the model construction can be deterministically carried out in a vector space by matrix operations applied to the matricized version of a dualized logic program $\mathrm{DB}^{d}$ of $\mathrm{DB} . \mathrm{DB}^{d}$ is a finite definite clause program compiled from DB and used to compute DB's success set $P_{\infty}$ as true atoms, and DB's finite failure set $N_{\infty}$ as false atoms. They constitute the least 3 -valued model $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ of $\operatorname{comp}(\mathrm{DB})$. We then construct a 2 -valued model of $\operatorname{comp}(\mathrm{DB})$, i.e. supported model (Apt et al., 1988; Marek and V.S.Subrahmanian, 1992) of DB by appropriately assigning $\mathbf{t}$ or $\mathbf{f}$ to undefined atoms not in $P_{\infty}$ or $N_{\infty}$ so that the resulting model is 2 -valued and supported. Every supported model of DB is obtained this way. The assignment process is guided by an atom dependency relation on undefined atoms and processes them from bottom-layers. Since every true (resp.
false) atom in $I_{\infty}$ remains true (resp. false) in any supported model of DB, we may say that $I_{\infty}$ represents the "deterministic part" of supported models (or stable models) of DB. To our knowledge, our approach is the first that computes 3-valued completion semantics in vector spaces and also the first that computes the deterministic part of supported models separately.

## 2 PRELIMINARIES

In this paper, programs mean finite propositional normal logic programs DB made up of a set of atoms $\mathcal{A}$ unless otherwise stated. Write $\mathrm{DB}=\left\{a_{i} \leftarrow B_{i} \mid 1 \leq i \leq\right.$ $\left.N, a_{i} \in \mathcal{A}\right\}$ where $B_{i}$ is a conjunction of literals whose atoms are in $\mathcal{A}^{1}$. Let $a \leftarrow B_{1}, \ldots, a \leftarrow B_{k}$ be clauses about $a$ in DB. Introduce new constant atoms true and false respectively denoting $\mathbf{t}$ and $\mathbf{f}$. We define the iff (if-and-only-if) completion about $a$ as follows.

If $k=0$, i.e. there is no clause about $a$, put $\operatorname{iff}(a)=a \Leftrightarrow \mathrm{false}$. If $k=1$ and $B_{1}$ is an empty conjunction, i.e. $a$ is a unit clause, put $\operatorname{iff}(a)=a \Leftrightarrow$ true. Otherwise put iff $(a)=a \Leftrightarrow B_{1} \vee \cdots \vee B_{k}$. The completion of DB , denoted by $\operatorname{comp}(\mathrm{DB})$, is defined as $\operatorname{comp}(\mathrm{DB})=\{\operatorname{iff}(a) \mid a \in \mathcal{A}\}$.

We consider 3-valued completion semantics of logic programs following Fitting and Kunen(Fitting, 1985; Kunen, 1987). Their semantics is based on Kleene's 3 -valued logic that has three truth values \{ $\mathbf{t}$ (true), $\mathbf{f}$ (false), $\perp$ (undefined) \}. In Kleene's 3-valued logic, when neither $A$ nor $B$ is $\perp$, conjunction $A \wedge B$, disjunction $A \vee B$ and negation $\neg A$ are evaluated as usual. However, if one of them is $\perp$, we obey the following rules; $A \wedge B=\perp$ iff one conjunct is $\perp$ and the other is not false, $A \vee B=\perp$ iff one disjunct is $\perp$ and the other is not true, and $\neg A=\perp$ iff $A=\perp$. We treat implication $A \leftarrow B$ as $\neg A \vee B$. Accordingly $\perp \leftarrow \perp=$ $\perp$.

A 3-valued interpretation $I$ in $\mathcal{A}$ is a pair $(P, N)$ such that $P \cup N \subseteq \mathcal{A}$ and $P \cap N=\emptyset$ where $P$ stands for true atoms and $N$ for false atoms. We next define $\left[F F \rrbracket_{I} \in\{\mathbf{t}, \mathbf{f}, \perp\}\right.$, i.e. the truth value of a Boolean formula $F$ evaluated by $I=(P, N)$. We first define $\llbracket$ true $\rrbracket_{I}=\mathbf{t}$ and $\left[\llbracket \mathrm{false} \rrbracket_{I}=\mathbf{f}\right.$, then define $\llbracket F \rrbracket_{I}$ for $F=a \in \mathcal{A}$ by $[\llbracket a]_{I}=\mathbf{t}, \mathbf{f}$ and $\perp$ respectively if $a \in P$, $a \in N$ and otherwise and extend the definition to compound Boolean formulas according to Kleene's 3valued logic.

Since we are interested in comp(DB), in particular in $\operatorname{iff}(a)=a \Leftrightarrow B_{1} \vee \cdots \vee B_{k}$ and the equality of truth values of $a$ and $B_{1} \vee \cdots \vee B_{k}$, we deviate here from

[^1]Kleene's 3-valued logic and interpret $\Leftrightarrow$ in a 2-valued way. We stipulate that $[A \Leftrightarrow B]_{I}=\mathbf{t}$ if $[A A]_{I}=\left[[B]_{I}\right.$. Otherwise $[A \Leftrightarrow B]_{I}=\mathbf{f}$. So $[\perp \Leftrightarrow \perp]_{I}=\mathbf{t}$ and $[[\perp \Leftrightarrow$ $\mathbf{t}]_{I}=\mathbf{f}$. If $[\operatorname{iff}(a)]_{I}=\mathbf{t}$ holds for every $a \in \mathcal{A}$, we call $I$ a 3-valued model of comp(DB) or equivalently a 3-valued completion model of DB ${ }^{2}$.

It is known that Fitting's 3-valued semantics of normal logic programs is highly undecidable whereas Kunen's 3 -valued one is recursively enumerable (Fitting, 1985; Kunen, 1987), but they coincide in the case of finite propositional normal logic programs, which we describe next. Here we inductively define a series of 3-valued interpretations $I_{0}=\left(P_{0}, N_{0}\right), I_{1}=$ $\left(P_{1}, N_{1}\right), \ldots$ (Sato, 1990).

```
(base case) \(P_{0}=N_{0}=\emptyset\)
(inductive step)
    Put \(I_{n-1}=\left(P_{n-1}, N_{n-1}\right)\)
    \(P_{n}=\left\{a \in \mathcal{A} \mid\right.\) there is \(a \leftarrow B\) in DB s.t. \(\left[[B]_{I_{n-1}}=\mathbf{t}\right\}\)
    \(N_{n}=\left\{a \in \mathcal{A} \mid\right.\) for all \(a \leftarrow B\) in DB, \(\left.[[B]]_{I_{n-1}}=\mathbf{f}\right\}\)
```

    Figure 1: Defining 3-valued interpretations \(\left\{\left(P_{n}, N_{n}\right)\right\}\).
    It is straightforward to verify \(P_{n} \cap N_{n}=\emptyset(\mathrm{n}=0,1 \ldots)\),
    and hence \(I_{n}=\left(P_{n}, N_{n}\right)\) is a 3 -valued interpretation.
    Let \(\left(A_{1}, A_{2}\right)\) and ( \(B_{1}, B_{2}\) ) be pairs of sets. We in-
    troduce a partial ordering " \(\sqsubseteq\) " on pairs of sets by
    \(\left(A_{1}, A_{2}\right) \sqsubseteq\left(B_{1}, B_{2}\right)\) iff \(A_{1} \subseteq B_{1}\) and \(A_{2} \subseteq B_{2}\). Now
    we see \(I_{0} \sqsubseteq I_{1} \sqsubseteq \cdots\) (Sato, 1990). We introduce \(P_{\infty}\)
    by \(P_{\infty}=\bigcup P_{n}\) and \(N_{\infty}\) by \(N_{\infty}=\bigcup N_{n}\) respectively and
    put $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$.

We list some propositions (see (Sato, 1990) for proofs).
Proposition 1. $I_{\infty}$ is a 3-valued model of $\operatorname{comp}(D B)$.
Proposition 2. $I_{\infty}$ is the least 3-valued model of comp $(D B)$ in the sense of $\sqsubseteq$-ordering.

It is apparent that when DB is a definite clause program, $P_{\infty}$ in $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ gives the success set of DB, i.e. the least 2-valued model of DB (whereas $N_{\infty}$ gives the finite failure set of DB ). We consider the least 3 -valued model $I_{\infty}$ as the denotation of DB in our 3-valued semantics.

A 2 -valued completion model of DB, i.e. a 2valued interpretation satisfying $\operatorname{comp}(\mathrm{DB})$, is called a supported model of DB (Apt et al., 1988; Marek and V.S.Subrahmanian, 1992). DB may have no supported model (think of $a \leftarrow \neg a$ ) but if DB has a supported model represented by a set $P_{s}(\subseteq \mathcal{A})$, we see $I_{\infty} \sqsubseteq I_{s}=\left(P_{s}, \mathcal{A} \backslash P_{s}\right)$ thanks to Proposition 2 because every 2 -valued completion model is also a 3valued completion model. In other words, every sup-

[^2]ported model is obtained by appropriately assigning $\mathbf{t}$ or $\mathbf{f}$ to the undefined atoms in $U_{\infty}=\mathcal{A} \backslash\left(P_{\infty} \cup N_{\infty}\right)$. Supported models are a super class of stable models and when DB is tight (no looping caller-callee chain through positive goals), DB's supported models and DB's stable models coincide (Erdem and Lifschitz, 2003).
\[

$$
\begin{aligned}
\mathrm{DB}_{0} & =\left\{\begin{array}{l}
\mathrm{a} \leftarrow \neg \mathrm{~b} \wedge \mathrm{c} \\
\mathrm{~b} \leftarrow \neg \mathrm{a} \wedge \mathrm{c} \\
\mathrm{c} \leftarrow \neg \mathrm{~d}
\end{array}\right. \\
\operatorname{comp}\left(\mathrm{DB}_{0}\right) & =\left\{\begin{array}{l}
\mathrm{a} \Leftrightarrow \neg \mathrm{~b} \wedge \mathrm{c} \\
\mathrm{~b} \Leftrightarrow \neg \mathrm{a} \wedge \mathrm{c} \\
\mathrm{c} \Leftrightarrow \neg \mathrm{~d} \\
\mathrm{~d} \Leftrightarrow \mathrm{false}
\end{array}\right.
\end{aligned}
$$
\]

Figure 2: A program $\mathrm{DB}_{0}$ and its completion $\operatorname{comp}\left(\mathrm{DB}_{0}\right)$.
Look at $\mathrm{DB}_{0}$ in Figure 2. We see $\left(P_{0}, N_{0}\right)=$ $(\emptyset, \emptyset),\left(P_{1}, N_{1}\right)=(\emptyset,\{\mathrm{d}\}),\left(P_{2}, N_{2}\right)=(\{\mathrm{c}\},\{\mathrm{d}\})$ and $\left(P_{3}, N_{3}\right)=\left(P_{2}, N_{2}\right)=I_{\infty}$. Then $\{\mathrm{a}, \mathrm{b}\}$ are undefined atoms $U_{\infty}$ in $I_{\infty}$. So any supported model of $\mathrm{DB}_{0}$ is obtained by assigning $\mathbf{t}$ or $\mathbf{f}$ to each of a and b appropriately. Actually $(\{a, c\},\{b, d\})$ and $(\{b, c\},\{a, d\})$ exhaust all supported models of $\mathrm{DB}_{0}$.

## 3 MATRICIZING 3-VALUED SEMANTICS

We here compute $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ in a vector space by matrix. As a preprocessing step, we standardize a program first and then represent the standardized program by a $0-1$ matrix.

### 3.1 Standardization

Let DB be a program, $\mathcal{A}$ the set of all atoms appearing in DB. For every atom $a \in \mathcal{A}$, do the following.

- If $a$ has no clause about it , add $a \leftarrow \mathrm{f}$ alse to DB.
- If $a$ has a unit clause $a \leftarrow$, replace it with $a \leftarrow$ true.
- If there is more than one clause $\left\{a \leftarrow B_{1}, \ldots, a \leftarrow\right.$ $\left.B_{k}\right\}(k>1)$ in DB, replace them with a set of new clauses $\left\{a \leftarrow b_{1} \vee \cdots \vee b_{k}, b_{1} \leftarrow B_{1}, \ldots, b_{k} \leftarrow B_{k}\right\}$ containing new atoms $\left\{b_{1}, \ldots, b_{k}\right\}$.

Call the resulting program a standardized program of DB. In general, if a program is standardized, every atom $a$ in $\mathcal{A}$ has exactly one clause $a \leftarrow B$ about it and $B$ is true, false, a conjunction or disjunction of literals in $\mathcal{A}$.

Proposition 3. Let $D B^{\prime}$ be a standardized program of $D B$. Then $\operatorname{comp}\left(D B^{\prime}\right)$ and $\operatorname{comp}(D B)$ have the same 3 -valued completion models as far as atoms in $\mathcal{A}$ are concerned (proof omitted).

Proposition 3 tells us that to compute a 3-valued model of comp (DB), we may assume DB is standardized. So, hereafter, we only deal with standardized programs.

### 3.2 Dualized Logic Programs

Here we introduce dualized programs for later use. Let $\mathrm{DB}=\left\{a_{i} \leftarrow B_{i} \mid 1 \leq i \leq N\right\}$ be a standardized program in a set of atoms $\mathscr{A}=\left\{a_{1}, \ldots, a_{N}\right\}$. We define a definite clause program $\mathrm{DB}^{d}$ called a dualized program of DB that can compute DB's least 3-valued completion model $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ as its least 2-valued model.

First introduce a set of new atoms $\overline{\mathcal{A}}=$ $\left\{n a_{1}, \ldots, n a_{N}\right\}$. The idea is that $n a_{i}$ represents $\neg a_{i}$ by negation-as-failure (NAF), i.e. an SLD derivation with NAF for $a_{i}$ finitely fails. We now define a syntactic function $n(\cdot)$ as follows. First put $n($ true $)=$ false and $n(f a l s e)=$ true. Next consider literals. Let $l$ be a literal whose atom is in $\mathcal{A}$. If $l$ is an atom $a$, define $n(l)=n a$. Otherwise $l$ is a negated atom $\neg a$ and put $n(l)=a$. We extend $n(\cdot)$ to conjunction and disjunction by defining $n\left(l_{1} \wedge \cdots \wedge l_{m}\right)=n\left(l_{1}\right) \vee \cdots \vee$ $n\left(l_{m}\right)$ and $n\left(l_{1} \vee \cdots \vee l_{m}\right)=n\left(l_{1}\right) \wedge \cdots \wedge n\left(l_{m}\right)$. Also we apply $n(\cdot)$ to a set $S$ by $n(S)=\{n(a) \mid a \in S\}$.

Dually we introduce a function $p(\cdot)$ s.t. $p($ true $)=$ true and $p($ false $)=$ false. For atoms in $\mathcal{A}$, if $l$ is an atom $a$, put $p(l)=a$. Otherwise $l=\neg a$ and put $p(l)=n a . p(\cdot)$ is extended to conjunction and disjunction by $p\left(l_{1} \wedge \cdots \wedge l_{m}\right)=p\left(l_{1}\right) \wedge \cdots \wedge p\left(l_{m}\right)$ and $p\left(l_{1} \vee \cdots \vee l_{m}\right)=p\left(l_{1}\right) \vee \cdots \vee p\left(l_{m}\right)$.

Finally define a dualized program $\mathrm{DB}^{d}$ of DB. It is a definite clause program and defined by $\mathrm{DB}^{d}=$ $\{a \leftarrow p(B), n a \leftarrow n(B) \mid a \leftarrow B \in \mathrm{DB}\}$. Note that if DB is standardized, so is $\mathrm{DB}^{d}$.

Look at $\mathrm{DB}_{1}$ in Figure 3. It is a standardization of $\mathrm{DB}_{0}$ in Figure 2. Notice that the least 2-valued model of $\mathrm{DB}_{1}^{d}$ is $\{\mathrm{c}, \mathrm{nd}\}$ and it exactly corresponds to the least 3 -valued model $(\{c\},\{d\})$ of $\operatorname{comp}\left(\mathrm{DB}_{1}\right)$. This is not a coincidence. We next prove that $\mathrm{DB}^{d}$ computes the least 3 -valued model $I_{\infty}$ of $\operatorname{comp}(\mathrm{DB})$ as its least 2 -valued model.

Put $\overline{\mathcal{A}}=\{n a \mid a \in \mathcal{A}\}$ and $\mathcal{A}^{d}=\mathcal{A} \cup \overline{\mathcal{A}}$. Equate $J \subseteq \mathcal{A}^{d}$ with a 2 -valued interpretation s.t. $\llbracket[c]_{J}=\mathbf{t}$ iff $c \in J$ for an atom $c \in \mathscr{A}^{d}$. Now define a series of 2-valued interpretations $\left\{J_{n}\left(\subseteq \mathscr{A}^{d}\right)\right\}$ for $\mathrm{DB}^{d}$ by $J_{0}=\emptyset$ and $J_{n}=\left\{c \mid c \leftarrow D \in \mathrm{DB}^{d},[[D]]_{J_{n-1}}=\mathbf{t}\right\}$. We have $\emptyset=J_{0} \subseteq J_{1} \subseteq \ldots$ and $J_{\infty}=\bigcup_{n} J_{n}$ gives the least 2 -valued model of $\mathrm{DB}^{d}$ as usual. We call $\left\{J_{n}\right\}$ the

$$
\begin{aligned}
& \mathrm{DB}_{1}=\left\{\begin{array}{l}
\mathrm{a} \leftarrow \neg \mathrm{~b} \wedge \mathrm{c} \\
\mathrm{~b} \leftarrow \neg \mathrm{a} \wedge \mathrm{c} \\
\mathrm{c} \leftarrow \neg \mathrm{~d} \\
\mathrm{~d} \leftarrow \mathrm{false}
\end{array}\right. \\
& \mathrm{DB}_{1}{ }^{d}=\left\{\begin{array}{l}
\mathrm{a} \leftarrow \mathrm{nb} \wedge \mathrm{c} \\
\mathrm{~b} \leftarrow \mathrm{na} \wedge \mathrm{c} \\
\mathrm{c} \leftarrow \mathrm{nd} \\
\mathrm{~d} \leftarrow \mathrm{false} \\
\mathrm{na} \leftarrow \mathrm{~b} \vee \mathrm{nc} \\
\mathrm{nb} \leftarrow \mathrm{a} \vee \mathrm{nc} \\
\mathrm{nc} \leftarrow \mathrm{~d} \\
\mathrm{nd} \leftarrow \text { true }
\end{array}\right.
\end{aligned}
$$

Figure 3: Standardized program $\mathrm{DB}_{1}$ and its dual program $\mathrm{DB}_{1}^{d}$.
defining interpretations associated with $J_{\infty}$. The following theorem is proved.

Theorem 1. Suppose DB is a standardized normal logic program and $D B^{d}$ is the dualized program of $D B$. Let $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ be the least 3-valued model of $\operatorname{comp}(D B)$ and $J_{\infty}$ the least 2-valued model of $D B^{d}$ respectively. Then we have $\left(P_{\infty}, n\left(N_{\infty}\right)\right)=\left(\mathcal{A} \cap J_{\infty}, \overline{\mathcal{A}} \cap\right.$ $\left.J_{\infty}\right)$ (proof omitted).

### 3.3 Matricized Logic Programs

Theorem 1 tells us that the least 3-valued model $I_{\infty}=$ $\left(P_{\infty}, N_{\infty}\right)$ of $\operatorname{comp}(\mathrm{DB})$ can be computed as the least 2-valued model $J_{\infty}$ of $\mathrm{DB}^{d}$. Here we point out that $J_{\infty}$ is conveniently computable in a vector space using matrix operations. Our linear algebraic approach to completion semantics is motivated to exploit rapidly growing computer power enabled by modern parallel computation technologies such as multicores and GPUs.

Let $\mathrm{DB}=\left\{a_{1} \leftarrow B_{1}, \ldots, a_{N} \leftarrow B_{N}\right\}$ be a standardized normal logic program where the bodies $B_{i}$ 's are either true, false, a conjunction or disjunction of atoms in $\mathcal{A}=\left\{a_{1}, \ldots, a_{N}\right\}$. Write the dualized program as $\mathrm{DB}^{d}=\left\{a_{1} \leftarrow B_{1}, \ldots, a_{N} \leftarrow B_{N}\right.$, $\left.n a_{1} \leftarrow n B_{1}, \ldots, n a_{N} \leftarrow n B_{N}\right\}$. We represent $\mathrm{DB}^{d}$ in terms of a $(2 N \times 2 N) 0-1$ matrix $Q$ and a $(2 N \times 1)$ threshold vector $\theta^{3} . Q$ is said to be a matricized $\mathrm{DB}^{d}$ or a program matrix for $\mathrm{DB}^{d}$. We construct $Q$ and $\theta$ by a procedure in Figure $4{ }^{4}$.

[^3]- Initialize $Q$ to a $(2 N \times 2 N)$ zero matrix.
- For $i(1 \leq i \leq N)$, do the following;

If $B_{i}=$ true, set $Q(i, i)=\theta(i)=1$.
If $B_{i}=\mathrm{false}$, set $Q(i+N, i+N)=\theta(i)=1$.
Otherwise, let $a_{i} \leftarrow B_{i}$ and $n a_{i} \leftarrow n B_{i}$ be clauses
about $a_{i}$ and $n a_{i}$ in $\mathrm{DB}^{d}$ respectively.

- If $B_{i}$ is a conjunction with $\left|B_{i}\right|>1$, set $\theta(i)=$ $\left|B_{i}\right|$ and $\theta(i+N)=1$.
- Otherwise $B_{i}$ is a disjunction. Set $\theta(i)=1$ and $\theta(i+N)=\left|n B_{i}\right|$.
- Write $B_{i}$ as $l_{1} \diamond \cdots \diamond l_{m}(m>0)$ where $\diamond$ denotes either $\wedge$ or $\vee$.
For $p(1 \leq p \leq m)$,
If $l_{p}$ is an atom $a_{j}$,
put $Q(i, j)=Q(i+N, j+N)=1$.
Else $l_{p}$ is a negated atom $\neg a_{j}$ and
$\operatorname{set} Q(i, j+N)=Q(i+N, j)=1$.
Figure 4: Constructing a program matrix $Q$ and a threshold vector $\theta$ for $\mathrm{DB}^{d}$.

For $i(1 \leq i \leq N)$, the body $B_{i}$ of $a_{i} \leftarrow B_{i}$ in $\mathrm{DB}^{d}$ is encoded as the $i$-th row $Q(i,:)$ of $Q$ whereas the body $n B_{i}$ of $n a_{i} \leftarrow n B_{i}$ is encoded as the $i+N$-th row $Q(i+N,:)$ of $Q$. More specifically, for $k(1 \leq k \leq 2 N)$, when $\theta(k)>1, Q(k,:)$ represents a conjunction of atoms in $\mathcal{A}^{d}$. However, if $\theta(k)=1, Q(k,:)$ may represent true, false or a disjunction. We disambiguate them as follows. If $Q(k,:)$ is a zero vector, $Q(k,:)$ represents $c_{k} \leftarrow \mathrm{false} \in \mathrm{DB}^{d}$. If $Q(k, k)=1$ and $(Q(k+N,:)$ or $Q(k-N,:)$ is a zero vector), $Q(k,:)$ represents $c_{k} \leftarrow$ true $\in \mathrm{DB}^{d}$. Otherwise $Q(k,:)$ is a disjunction of atoms in $\mathcal{A}^{d}$. Thus $\mathrm{DB}^{d}$ is recoverable from $Q$ and $\theta$.

An $(8 \times 8)$ matrix $Q_{1}$ below is a program matrix for $D B_{1}$ in Figure 3. As we can see, $\mathrm{a} \leftarrow \mathrm{nb} \wedge \mathrm{c}$ is encoded by $Q_{1}(1,:)=(00100100), \mathrm{d} \leftarrow$ false by $Q_{1}(4,:)=(00000000)$, and nd $\leftarrow$ true by $Q_{1}(8,:$ $)=(00000001)$. Also we set $\theta(1)=|\mathrm{nb} \wedge \mathrm{c}|=2$ as the threshold associated with a conjunctive clause $\mathrm{a} \leftarrow \mathrm{nb} \wedge \mathrm{c}$ while we set $\theta(5)=1$ for $\theta(5)$ associated with a disjunctive clause $\mathrm{na} \leftarrow \mathrm{b} \vee \mathrm{nc}^{5}$.

We compute the least 2 -valued model $J_{\infty}$ of $\mathrm{DB}^{d}$ numerically using $Q$ in a vector space. Let $J\left(\subseteq \mathscr{A}^{d}\right)$ be an interpretation for $\mathrm{DB}^{d}$. $J$ is represented by a $2 N$ dimensional 0-1 vector $\mathbf{u}^{(J)}$ which is constructed as follows. For $i(1 \leq i \leq N)$, put $\mathbf{u}^{(J)}(i)=1$ if $a_{i} \in J$. Otherwise $\mathbf{u}^{(J)}(i)=0$. Similarly put $\mathbf{u}^{(J)}(i+N)=1$ if $n a_{i} \in J$ and otherwise $\mathbf{u}^{(J)}(i+N)=0$.

[^4]\[

Q_{1}=$$
\begin{array}{cccccccc}

\end{array}
$$\right)
\]

Figure 5: A program matrix $Q_{1}$ and a threshold vector $\theta_{1}$ for $\mathrm{DB}_{1}^{d}$.

We here introduce a thresholding notation $(x)_{\geq \theta}$ parameterized with a real number $\theta$ by $(x)_{\geq \theta}=1$ if $x \geq \theta$. Otherwise $(x)_{\geq \theta}=0$. We further extend $(x)_{\geq \theta}$ to a vector notation $(\mathbf{u})_{\geq \theta}$ with a threshold vector $\theta$ in such a way that $(\mathbf{u})_{\geq \theta}(i)=(\mathbf{u}(i))_{\geq \theta(i)}(1 \leq i \leq n)$ when $\mathbf{u}$ and $\theta$ are $n$ dimensional vectors.

Now consider the $k$-th clause $c_{k} \leftarrow D_{k} \in \mathrm{DB}^{d}(1 \leq$ $k \leq 2 N)$ and let $Q(k,:)$ be the $k$-th row encoding $D_{k}$. By construction, $Q(k,:) \mathbf{u}^{(J)}$ gives the number literals in $D_{k}$ which are true in $J$. Hence when $D_{k}$ is a conjunction, $D_{k}$ is true in $J$ iff $Q(k,:) \mathbf{u}^{(J)}=\left|D_{k}\right|(=\theta(k))$, or equivalently $\left[\left[D_{k}\right]_{J}=\left(Q(k,:) \mathbf{u}^{(J)}\right)_{>\theta(k)}{ }^{6}\right.$. Similarly, if $D_{k}$ is a disjunction, we set $\theta(k)=1$ and have $\left[\left[D_{k}\right]_{J}=\left(Q(k,:) \mathbf{u}^{(J)}\right)_{\geq \theta(k)}\right.$. Thus in either case, the clause body $D_{k}$ of $c_{k} \leftarrow D_{k}$ is evaluated by $J$ as $\left[\left[D_{k}\right]_{J}=\left(Q\left(k,:: \mathbf{u}^{(J)}\right)_{\geq \theta(k)}\right.\right.$, purely in a vector space in terms of matrix multiplication and thresholding. We summarize the argument so far as
Proposition 4. Let $D B=\left\{a_{1} \leftarrow B_{1}, \ldots, a_{N} \leftarrow B_{N}\right\}$ be a standardized normal logic program in atoms $\mathcal{A}=\left\{a_{1}, \ldots, a_{N}\right\}, D B^{d}$ the dualized logic program of $D B, J_{\infty}$ the least 2 -valued model of $D B^{d}, Q$ a program matrix and $\theta$ a threshold vector for $D B^{d}$. Compute a $2 N$ dimensional vector $\mathbf{u}_{\infty}=\mathbf{u}^{\left(J_{\infty}\right)}$. Then $\mathbf{u}_{\infty}$ satisfies $\mathbf{u}_{\infty}=\left(Q \mathbf{u}_{\infty}\right) \geq \theta$ (proof omitted).

Proposition 4 says that $\mathbf{u}_{\infty}$ is a fixedpoint vector of $f(\mathbf{u})=(Q \mathbf{u})_{\geq \theta}$ but does not tell us how to compute it, in particular, in a solely linear algebraic way.
Proposition 5. Let $\left\{J_{n}\right\}$ be the defining interpretations associated with the least model $J_{\infty}$ of $D B^{d}$. De-

[^5]fine a series of 0-1 vectors $\left\{\mathbf{u}_{n}\right\}$ by $\mathbf{u}_{1}=\mathbf{u}^{\left(J_{1}\right) 7}$ and $\mathbf{u}_{n+1}=\left(Q \mathbf{u}_{n}\right)_{\geq \theta}$. Then $\mathbf{u}_{n}=\mathbf{u}^{\left(J_{n}\right)}$ for all $n \geq 1$ and $\lim _{n} \mathbf{u}_{n}=\mathbf{u}_{\infty}$ (proof omitted).

We restate Proposition 5 as the least 3 -valued model computation procedure in Figure 6. Given a dualized program $\mathrm{DB}^{d}$ of a standardized normal logic program $\mathrm{DB}=\left\{a_{1} \leftarrow B_{1}, \ldots, a_{N} \leftarrow B_{N}\right\}$, it computes the least 2 -valued model $J_{\infty}$ of $\mathrm{DB}^{d}$ as a $2 N$ dimensional 0-1 vector $\mathbf{u}_{\infty}$ s.t. $\mathbf{u}_{\infty}=\mathbf{u}^{\left(J_{\infty}\right)}$, using a program matrix $Q$ and a threshold vector $\theta$ for $\mathrm{DB}^{d}$.

Step 1: Compute $\mathbf{u}_{1}=\mathbf{u}^{\left(J_{1}\right)}$
Step 2: Iterate for $n=1,2 \ldots$

$$
\mathbf{u}_{n+1}=\left(Q \mathbf{u}_{n}\right)_{\geq \theta} \text { until } \mathbf{u}_{n+1}=\mathbf{u}_{n}
$$

Step 3: Return $\mathbf{u}_{\infty}=\mathbf{u}_{n}$
Figure 6: Computing $\mathbf{u}_{\infty}$ by a program matrix $Q$ and a threshold vector $\theta$.

Applying the procedure in Figure 6 to $\mathrm{DB}_{1}^{d}$, we see $\mathbf{u}_{1}=\left(\begin{array}{llllllll}0 & 0 & 0 & 0 & 0 & 0 & 0 & 1\end{array}\right)^{T}$, $\mathbf{u}_{2}=\left(Q_{1} \mathbf{u}_{1}\right)_{\geq \theta_{1}}=\left(\begin{array}{llllllll}0 & 0 & 1 & 0 & 0 & 0 & 0 & 1\end{array}\right)^{T}$, $\mathbf{u}_{3}=\left(Q_{1} \mathbf{u}_{2}\right)_{\geq \theta_{1}}=\left(\begin{array}{llllll}0 & 0 & 1 & 0 & 0 & 0\end{array} 01\right)^{T}=\mathbf{u}_{2}$. Hence $\mathbf{u}_{\infty}=\mathbf{u}_{2}=\left(\begin{array}{llllll}0 & 0 & 1 & 0 & 0 & 0\end{array} 01\right)^{T}$ which coincides with $\mathbf{u}^{\left(J_{\infty}\right)}$ encoding $J_{\infty}=\{\mathrm{c}, \mathrm{nd}\}$ for $\mathrm{DB}_{1}^{d}$ that corresponds to the least 3 -valued model $(\{c\},\{d\})$ of $\operatorname{comp}\left(\mathrm{DB}_{0}\right)$.

The procedure in Figure 6 shows that it is possible to compute the least model semantics purely within vector spaces, but unfortunately, it takes $\mathrm{O}\left((2 N)^{3}\right)$ time if implemented naively using matrix multiplication. On the other hand, although we do not explain algorithmic details here, it is possible to compute the least model of Horn clause programs by matrix operations in $\mathrm{O}(\operatorname{size}(|\mathrm{DB}|))$ time by an elaborated implementation where $\operatorname{size}(\mathrm{DB})$ is the number of atoms occurring in DB.

## 4 SUPPORTED MODEL COMPUTATION

Suppose a program DB $=\left\{a_{1} \leftarrow B_{i}, \ldots, a_{N} \leftarrow B_{N}\right\}$ in $\mathcal{A}=\left\{a_{1}, \ldots, a_{N}\right\}$ is given and the least 3-valued model $I_{\infty}=\left(P_{\infty}, N_{\infty}\right)$ of $\operatorname{comp}(\mathrm{DB})$ has been computed. Put $U_{\infty}=\mathcal{A} \backslash\left(P_{\infty} \cup N_{\infty}\right)$. Atoms $a$ in $U_{\infty}$ cause infinite computation, or looping computation when an SLD-derivation is applied to $\leftarrow a$. As stated before, every supported model can be obtained by appropriately assigning $\mathbf{t}$ or $\mathbf{f}$ to atoms in $U_{\infty}$. We construct a

[^6]supported model of DB by a divide-and-conquer approach. First we analyze $U_{\infty}$ and detect strongly connected components (SCCs) in $U_{\infty}$ explained next. We then process SCCs one by one, i.e. assign, from bottom SCCs upwards, $\mathbf{t}$ or $\mathbf{f}$ to atoms in each SCC to locally construct a supported model of the SCC. When this process is completed without failure, we have a supported model of DB.

In general, atoms in $U_{\infty}$ have caller-caller dependency specified by DB and we express it as a dependency graph $\mathrm{G}_{U_{\infty}}$ s.t. nodes are atoms in $U_{\infty}$ and there is a directed edge from a node $a_{i}$ to a node $a_{j}$ iff there is a clause $a_{i} \leftarrow B_{i}$ is in DB and $B_{i}$ contains $a_{j}$. An SCC is a set of atoms written as $[a]=\{a\} \cup\{b \mid$ there exist paths from $a$ to $b$ and from $b$ to $a$ in $\left.\mathrm{G}_{U_{\infty}}\right\}$ for some $a \in U_{\infty}$. Intuitively atoms in an SCC are those calling one another, directly or indirectly.

Note that SCCs in $\mathrm{G}_{U_{\infty}}$ have a natural partial ordering. Let $[a]$ and $[b]$ be two SCCs. If there is a path from $a$ to $b$ but not from $b$ to $a$, we write $[b] \prec[a]$. " $\prec$ " is a partial ordering on SCCs. Using " $\prec$ ", SCCs are reverse-topologically sorted like [ $S_{1}, S_{2} \ldots$ ] s.t. whenever $S_{i} \prec S_{j}, i<j$ holds. We can obtain this reverse-topologically sorted list by Tarjan's algorithm in $\mathrm{O}(|V|+|E|)$ time where $|V|$ is the number of nodes, $|E|$ the number of edges of $\mathrm{G}_{U_{\infty}}$.

Look at $\mathrm{DB}_{2}$ in Figure 7 which is a slight variant of $\mathrm{DB}_{1}$. The least 3 -valued model of $\operatorname{comp}\left(\mathrm{DB}_{2}\right)$ is $(\emptyset, \oslash)$ and all atoms are undefined, i.e. $U_{\infty}=$ $\{\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}\}$. There are two SCCs, $[\mathrm{a}]=[\mathrm{b}]=\{\mathrm{a}, \mathrm{b}\}$ and $[\mathrm{c}]=[\mathrm{d}]=\{\mathrm{c}, \mathrm{d}\}$, and $[\mathrm{c}] \prec[\mathrm{a}]$ holds. They are reverse-topologically sorted into a list $\mathrm{SCC}_{\mathrm{DB}_{2}}=$ $[\{c, d\},\{a, b\}]$.
$\mathrm{DB}_{2}=\left\{\begin{array}{l}\mathrm{a} \leftarrow \neg \mathrm{b} \wedge \mathrm{c} \\ \mathrm{b} \leftarrow \neg \mathrm{a} \wedge \mathrm{c} \quad \mathrm{SCC}_{\mathrm{DB}_{2}}=[\{\mathrm{c}, \mathrm{d}\},\{\mathrm{a}, \mathrm{b}\}] \\ \mathrm{c} \leftarrow \neg \mathrm{d}] \\ \mathrm{d} \leftarrow \neg \mathrm{c}\end{array}\right.$
Figure 7: $\mathrm{DB}_{2}$ having two SCCs.
Let $\mathrm{SCC}_{\mathrm{DB}}=\left[\mathrm{SCC}_{1}, \mathrm{SCC}_{2}, \ldots\right]$ be a reversetopologically sorted list of SCCs in $U_{\infty}$. We build a supported model of DB by processing those SCCs from left-to-right. Suppose $\mathrm{SCC}_{j} \mathrm{~s}(j<i)$ preceding $\mathrm{SCC}_{i}$ have been processed and their atoms are already assigned $\mathbf{t}$ or $\mathbf{f}$. Write $\mathrm{SCC}_{i}=\left\{b_{1}, \ldots, b_{K}\right\}$ and let $\mathrm{DB}_{i}^{\mathrm{SCC}}=\left\{b_{j} \leftarrow W_{j} \mid 1 \leq j \leq K\right\}$ be a subprogram of DB about atoms in $\mathrm{SCC}_{i}$. Since undefined atoms that appear in $\mathrm{DB}_{i}^{S C C}$ other than $\mathrm{SCC}_{i}$ are already assigned $\mathbf{t}$ or $\mathbf{f}$, we construct a supported model of $\mathrm{DB}_{i}^{\mathrm{SCC}}$ by appropriately assigning $\mathbf{t}$ or $\mathbf{f}$ to atoms in $\mathrm{SCC}_{i}$ when possible.

Our task w.r.t. $\mathrm{SCC}_{i}$ is to make every $b_{j} \Leftrightarrow W_{j}$ ( $1 \leq j \leq K$ ) in comp $\left(\mathrm{SCC}_{i}\right)$ true (in 2-valued logic) by
determining the truth values of $b_{1}, \ldots, b_{K}$. Although this is easily formulated as a SAT problem and solvable by a SAT solver, we would like to exploit the form of iff completion which is lost in translation to CNF. Suppose $\operatorname{iff}(b)=b \Leftrightarrow c \wedge \neg d$ is in $\mathrm{DB}_{i}^{S C C}$ and $\{b, c, d\}$ are all undefined. We have to find their truth values that make $\operatorname{iff}(b)$ true. Basically this is an exhaustive search but since $\operatorname{iff}(b)$ is an equivalence formula, the truth value of the atom $b$, once determined, propagates to the body atoms on the right-hand side. For example, if $\mathbf{t}$ is assigned to $b, c=\mathbf{t}$ and $d=\mathbf{f}$ necessarily follow for iff $(b)$ to be true. Or if $\mathbf{f}$ is assigned to $b$, we nondeterministically choose one of $\{c, \neg d\}$ and make the chosen literal false. Similarly for the disjunctive case such as $\operatorname{iff}(b)=b \Leftrightarrow c \vee \neg d$, an assignment $b=\mathbf{f}$ propagates to $c=\mathbf{f}$ and $d=\mathbf{t}$ in the body and so on. In this way, we make use of the iff completion to efficiently propagate truth values from one atom to another in $\mathrm{SCC}_{i}$.

We conclude this section with our search procedure for supported models in Figure 8. Suppose we are given a program DB in a set of propositional atoms $\mathcal{A}$.

Step 1: Compute the least 3-valued model $I_{\infty}=$ $\left(P_{\infty}, N_{\infty}\right)$ of $\operatorname{comp}(\mathrm{DB})$ via dualized program $\mathrm{DB}^{d}$ using the procedure in Figure 6 and extract undefined atoms $U_{\infty}=\mathcal{A} \backslash\left(P_{\infty} \cup N_{\infty}\right)$.
Step 2: Analyze $U_{\infty}$ and obtain a reversetopologically sorted list $\mathrm{SCC}_{\mathrm{DB}}=$ $\left\{\mathrm{SCC}_{1}, \ldots, \mathrm{SCC}_{M}\right\}$ of SCCs in $U_{\infty}$.
Step 3: For $i=1$ to $M$, assign appropriately truth values $\{\mathbf{t}, \mathbf{f}\}$ to atoms in $\mathrm{SCC}_{i}$ so that the total assignment constitutes a supported model of DB, i.e. a 2 -valued model of $\operatorname{comp}(\mathrm{DB})$.

Figure 8: Search procedure for a supported model of DB via dualized $\mathrm{DB}^{d}$.

## 5 EXPERIMENT

In this section, we conduct an experiment with supported model computation ${ }^{8}$ using the computation procedure described in Figure 8 which is implemented entirely by matrix operations provided by GNU Octave 4.2.2 ${ }^{9}$. Our experiment is intended to

[^7]show the effectiveness of 3 -valued model computation as a preprocessing step prior to 2 -valued model computation.

Computing the least 3 -valued model $I_{\infty}=$ $\left(P_{\infty}, N_{\infty}\right)$ of comp(DB) at Step 1 in Figure 8 has the effect of reducing the search space for supported model construction of DB by detecting atoms whose truth values are determined, or common to all supported models of DB. That is, since atoms in $P_{\infty}$ (resp. atoms in $N_{\infty}$ ) are true (resp. false) in any supported model of DB, we have only to consider truth value assignment for the remaining atoms, those in $U_{\infty}=\mathcal{A} \backslash\left(P_{\infty} \cup N_{\infty}\right)$ when searching for a supported model of DB.

We here conduct an experiment to measure the effect of Step 1 on search space reduction. First we introduce newly determined atoms. They are atoms whose truth values are "newly determined" at Step 1. By "newly determined", we mean those atoms in $\left(P_{\infty} \cup N_{\infty}\right) \backslash\left(P_{1} \cup N_{1}\right)$ because atoms in $P_{1} \cup N_{1}$ are unit clauses (facts) or atoms having no clauses about them, and hence their truth values are immediately known. Since newly determined atoms are removed from the search space for supported model construction, we measure the effect of search space reduction by "reduction_rate" defined by reduction_rate = \#newly_determined $/ n$ where \#newly_determined is the number of newly determined atoms and $n$ is the total number of atoms.

In this experiment, after setting the number of atoms $n=100$ and a probability $p=0.03$, we randomly generate a normal logic program $\mathrm{DB}_{(100,0.03)}$ in a set of propositional atoms $\mathcal{A}=\left\{a_{1}, \ldots, a_{100}\right\}$, compute its least 3 -valued completion model and count \#newly_determined_atom. When generating clauses in $\mathrm{DB}_{(100,0.03)}$, we specifically consider "base atoms" $\left\{a_{1}, \ldots, a_{10}\right\}$, and convert them to facts (unit clauses) $\left\{a_{1} \leftarrow, \ldots, a_{10} \leftarrow\right\}$ or to tautologies $\left\{a_{1} \leftarrow\right.$ $\left.a_{1}, \ldots, a_{10} \leftarrow a_{10}\right\}$. When base atoms are converted to facts, $\mathrm{DB}_{(100,0.03)}$ will have more newly determined atoms than are converted to tautologies. To generate clauses $a \leftarrow B$ for the remaining atoms $\left\{a_{11}, \ldots, a_{100}\right\}$, we randomly pick up atoms in $\mathcal{A}$ with probability $p$, negate them with probability 0.5 and make a conjunction of resulting literals with probability 0.5 as the clause body $B$. Otherwise use their disjunction as $B$. Consequently, the body $B$ contains average $n \cdot p=100 \cdot 0.03=3$ atoms. We repeat this process 90 times and construct the remaining clauses about $\left\{a_{11}, \ldots, a_{100}\right\}$ in $\mathrm{DB}_{(100,0.03)}$.

Table. 1 depicts the statistics of this experiment (figures are average over 10 trials). There \#empty_body denotes the average number of atoms having no clause about them in the randomly generated $\mathrm{DB}_{(100,0.03)}$. Their truth values are $\mathbf{f}$
in every supported model of $\mathrm{DB}_{(100,0.03)}$. \#undef atom is the average number of undefined atoms in the least 3 -valued model of $\operatorname{comp}\left(\mathrm{DB}_{(100,0.03)}\right)$. \#newly_determined_atom is therefore computed as 100 - (\#undef_atom + \#zero_body +10 ) when $\left\{a_{1}, \ldots, a_{10}\right\}$ are converted to facts. Otherwise it is 100 - (\#undef_atom + \#zero_body).

In the former case (see as_facts column), we observe \#newly_determined_atom = 83.9 giving reduction_rate $=83.9 \%$. It means, on average, $83.9 \%$ of atoms are newly assigned $\mathbf{t}$ or $\mathbf{f}$ at Step 1 and removed from the search space for supported model construction. In the latter case (see as_tautology column) in which base atoms are converted to tautologies, we have more undefined atoms, resulting in a smaller \#newly_determined_atom, 45.1 on average, but still $45.1 \%$ of atoms get their truth values automatically determined and removed from the search space at Step 1. Although the effect of preprocessing by computing the deterministic part of supported models at Step 1 may vary depending on programs, as far as randomly generated programs in this experiment are concerned, we may say it greatly reduces the search space associated with supported model construction.

## 6 RELATED WORK

3 -valued semantics of logic programs has been developed primarily from a theoretical perspective (Fitting, 1985; Kunen, 1987; Van Gelder et al., 1991; Naish, 2006; Barbosa et al., 2019). Fitting generalized the $T_{P}$ operator associated with 2-valued logic programs $P$ to a 3-valued operator $\Phi_{P}$. He used Kleene's 3valued logic and transfinite induction, which is similar to the inductive definition of $\left\{\left(P_{n}, N_{n}\right)\right\}$ given in Figure 1 where $n$ is replaced by ordinals, and established the existence of the least 3 -valued model of arbitrary normal logic programs (Fitting, 1985). However his semantics is highly undecidable, goes far beyond computable relations (at the cost of induction up to the Church-Kleene ordinal, i.e. the smallest nonrecursive ordinal). Kunen later proposed to cut off Fitting's induction at $\omega$ and proved using a 3 -valued ultra power model construction that the notion of $\mathrm{DB} \models_{3} \phi$, a sentence $\phi$ being a 3 -valued logical consequence

Table 1: The number of newly determined atoms.

| base atoms | as_facts | as_tautology |
| :--- | :---: | :---: |
| $\left\{a_{1}, \ldots, a_{10}\right\}$ | 3.6 | 12.4 |
| \#empty_body | 3.5 | 42.5 |
| \#undef_atom | $83.9 \%$ | $45.1 \%$ |
| reduction_rate |  |  |

of a program DB, is recursively enumerable (Kunen, 1987). Van Gelder proposed well-founded semantics (Van Gelder et al., 1991). The denotation of a program $P$, well-founded partial model, is defined as the least fixed point of some monotonic operator $W_{P}$ associated with $P$, which gives a 3 -valued model of $\operatorname{comp}(P)$. However, since $W_{P}$ is asymmetric on the treatment of positive/negative occurrence of atoms in the clause body, well-founded semantics differs from our semantics; for example, $p$ in a program $\{p \leftarrow p\}$ receives $f$ in well-founded semantics.

Supported models of a program DB are 2-valued models of the completed program $\operatorname{comp}(\mathrm{DB})$ (Apt et al., 1988; Marek and V.S.Subrahmanian, 1992). They can represent solutions of a quite large class of combinatorial problems, and hence their efficient computation is of practical interest. Also it is wellknown that stable models used in answer set programming (ASP) are a subclass of supported models and when propositional programs are finite and tight, they are identical (Erdem and Lifschitz, 2003). Our proposal to use 3 -valued model computation as a preprocessing step to compute supported models looks new and is applicable to stable model computation as well. It eliminates, as the experiment in Section 5 shows, the extraneous need for finding the right assignment of $\{\mathbf{t}, \mathbf{f}\}$ to the deterministic part of supported models. On the other hand, in ASP, stable models (or supported models) are computed by highly developed SAT technologies as in clingo (Gebser et al., 2019). It is an interesting future topic to merge our matricized approach with existing ASP computation mechanism.

## 7 CONCLUSION

We proposed to compute the least 3 -valued completion model of a finite normal logic program DB in a vector space by first converting DB to an equivalent definite clause program $\mathrm{DB}^{d}$, the dualized version of DB , and then computing its least 2 -valued model in a vector space using a matrix representing $\mathrm{DB}^{d}$, which is translated back to the least 3 -valued completion model of DB. We then applied this 3-valued model computation to computing 2 -valued completion models of DB, i.e. supported models of DB which are a super class of stable models. We constructed them by appropriately assigning $\mathbf{t}$ or $\mathbf{f}$ to the undefined atoms in the least 3 -valued completion model of DB while guided by the completion form of clauses. We implemented the 2 -valued and 3 -valued completion model computation by matrix operations, and confirmed the effectiveness of 3-valued computation as a preprocessing step prior to 2 -valued model computation.

Assigning truth vales to undefined atoms found in this method is the next step to compute 2 -valued supported models, and verification of efficiency of this part will be reported in a full version of this paper.

    *This paper is based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO).

[^1]:    ${ }^{1}$ Throughout this paper, we assume that if a program has a unit clause $a \leftarrow$, there is no other clause about $a$ in the program.

[^2]:    ${ }^{2}$ Likewise, a 2 -valued model of $\operatorname{comp}(\mathrm{DB})$ is called a 2 -valued completion model of DB.

[^3]:    ${ }^{3} Q$ only stores information about occurrences of atoms in the clause body and does not make a distinction between conjunction and disjunction. So we need to record supplementary information $\theta$ to recover the original $\mathrm{DB}^{d}$.
    ${ }^{4}$ For a conjunction or disjunction $F$, we use $|F|$ to denote the number of literals occurring in $F$.

[^4]:    ${ }^{5}$ In this paper, a definite clause whose body is a conjunction (resp. disjunction) is called a conjunctive clause (resp. disjunctive clause).

[^5]:    ${ }^{6}$ We identify 1 with $\mathbf{t}$ and 0 with $\mathbf{f}$ where the context is clear.

[^6]:    ${ }^{7} J_{1}=\left\{a \mid a \leftarrow\right.$ true $\left.\in \mathrm{DB}^{d}\right\} \cup\left\{n a \mid n a \leftarrow\right.$ true $\left.\in \mathrm{DB}^{d}\right\}$. So $\mathbf{u}_{1}$ encodes unit clauses in $\mathrm{DB}^{d}$.

[^7]:    ${ }^{8}$ The experiment is conducted on a PC with $\operatorname{Intel}(\mathrm{R})$ Core(TM) i7-8650U CPU ( $\max 4 \mathrm{GHz}$ ), 16 GB memory.
    ${ }^{9}$ For example, to implement Step 2, we represent a dependency graph $G_{U_{\infty}}$ by an adjacency matrix and implement Tarjan's algorithm on it to compute SCCs.
